

A

Cell lines arise by outgrowth of a proliferative subset, not from one parental tissue

B Shared program of established cell lines

Wolbachia

- 2 of 3 untreated lineages lost infection after the primary stage
- Hypothesis: host division outpaces bacterial replication (dilution)
- Infected Dsim6B-wMel re-expresses *rpr*, *hid* vs. cured Dsim6B

Strength of evidence

Polycomb silencing of developmental loci	strong
Proliferative cells shift toward cell lines	moderate
PVR/Pvf2/MAPK loop (dashed)	weak
Wolbachia dilution (hypothesis)	untested

Pseudobulk DE with 4 lineages as replicates; Polycomb maps: embryo H3K27me3, S2 and BG3 Pc-state (modENCODE). Dashed lines mark weakly supported or untested links.
